Geyser sign
of the
Shoulder.

The **geyser sign** is the flow of arthrographic contrast or joint fluid from the glenohumeral joint across the acromioclavicular joint (ACJ) to form a supraclavicular collection. It is seen in some cases of long-standing rotator cuff tear and advanced degenerative change of the shoulder.

Pathology

- Chronic rotator cuff degenerative change and full-thickness tearing lead to instability of the humerus in the glenohumeral joint.
- Eventually, chronic impaction from the humeral head disrupts the inferior acromioclavicular joint capsule, and glenohumeral joint fluid "erupts" superiorly through the acromioclavicular interval from the subacromial-subdeltoid bursa and glenohumeral joint.

Plain radiography

- There is often a high riding humeral head abutting the acromion or acromioclavicular joint indicating rotator cuff tears. There may be signs also of rotator cuff arthropathy.

Conventional arthrography

- After injection of arthrogram solution into the glenohumeral joint, the solution will decompress and extend into the subacromial-subdeltoid bursa (through the cuff tear) and into the acromioclavicular joint.

Ultrasound

- Background advanced degenerative changes in the shoulder with a full-thickness rotator cuff tear, as with a bare humeral head sign
- Hypoechoic fluid collection above the acromioclavicular joint.
 - ensure that the collection is genuinely fluid and not an exuberant hypoechoic degenerative change of the acromioclavicular joint or mass with color Doppler

MRI

- Background advanced degenerative change in the shoulder with a full-thickness rotator cuff tear.
- **T2:** hyperintense fluid tracks from the glenohumeral joint space into the subdeltoid bursa and into acromioclavicular joint
